Abstract

Objective: To investigate the perceptions and approaches to leadership and leadership development of senior nurses and care home managers in an aged care residential facility.

Method: A descriptive phenomenological research approach was employed to support purposive sampling. A questionnaire (n=10) was used, followed by interviews (n=8). Analysis employed an SPSS and NVivo 0.6 computer programs, with manual data configuration as required.

Results: Participants saw a distinction between their role as leaders and managers and that their more clinically focused responsibilities favoured a greater affinity with clinical leadership. In addition, the attributes and characteristics of clinical leaders identified by participants were approachability, clinical skills, clinical knowledge, honesty, integrity, support for others and visibility in the clinical area.

Conclusion: The development and deployment of clinical leadership attributes are vital so that senior nurses and care home managers can play a more effective part in care provision and service improvement in the residential care environment.

Keywords: Clinical leadership; Aged care; Residential care leadership; Phenomenological research

Introduction

In Australia people are living longer and are also well supported with an excellent health system and social welfare structures [1]. Nevertheless, in Australia 80\% of people over the age of 65 have three or more chronic conditions and older people with chronic illnesses are the highest users of all health and aged care services [2]. The aged care sector, while facing increasing care and quality demands is also feeling: the impact of a reducing qualified nursing staff pool; a transient and mobile management and nursing workforce; the perception that their service is of lower status compared with acute and community nursing services; and the view, in some quarters, that resources in the field are poor. These perspectives are compounded by the view that most of the care is offered by unskilled workers who, along with the qualified workforce, are poorly paid [3-8].

In May 2010, the Australian Government announced that it would promote change in practice and build clinical leadership capacity [9]. Despite this high level initiative, limited research exists that explores and describes what clinical level leadership is, who the clinical leaders are and the characteristics and attributes of clinical leaders in aged care residential facilities [10-13].

With the challenges and opportunities that abound in the residential aged care sector, management skills and leadership approaches are considered vital for addressing and dealing effectively with developments in care provision and service improvement in the care home environment. However, while much is known about the impact of management and leadership in the corporate or industry sectors, little is known about how leadership is perceived or how leadership can facilitate effective change and impact positively on residential care, quality and staff attitudes.

Key Points

- Used data from questionnaires and interviews with senior nursing staff and care home managers at a residential care facility.
- The study investigated the perceptions of clinical leadership and approaches to leadership development.
- Participants described the characteristics or attributes they saw as vital for a clinical leader.
- Data was offered about how leadership skills were obtained and insights into the difference between leadership and management.
- Participants also identified the issues that may hinder or stifle clinical leadership development in the aged care environment and recommendations and suggestions were made that have implications for nursing practice.

Background and Literature Review

The research was undertaken because leadership is clearly recognised as a key factor in many areas of the health service [12,14-16]. As well, given the perceptions alluded to above investigating the practice of leadership and how leadership can be fostered in the aged

The aged care sector is vital for effectively establishing leadership's influence on quality care and improvements in the life of residents and staff in the residential care field. There are few empirically based, leadership focused studies identified in the literature and this study would set the scene for a fertile area of research that the Department of Health and Aging [15,16] recognise as key in developing quality and establishing accountability in the aged care arena.

Leadership and nursing

There is a wealth of literature that deals with the role, nature and purpose of nursing leadership, the value of developing and nurturing nurse leaders and the characteristics of nurse leaders. Publications about nursing leadership abound and address the nature and purpose of leadership and leadership styles [12,13,17-19]. Much of the literature reviewed uses the terms 'leadership' and 'management' interchangeably with little attempt to define either term [10-12,20-22] and as a result, much of it fails to clarify who the leaders are, other than deference to their hierarchical position [23]. The pool of information related to 'management' in the aged care arena is substantial, although literature related to 'leadership' in the aged care arena is shallow and would benefit from research to generate information and knowledge about the application and perception of leadership.

There are a number of reasons offered that support and justify this research:

1. The ability to generate leadership is clearly becoming recognised as a key factor in many areas of the health service [12,14-16]. Investigating the practice of leadership and how leadership can be fostered in the aged care sector is vital for effectively establishing leadership's influence on quality care and improvements in the life of residents and staff in the aged care area.

2. There are few empirically based, leadership focused studies identified in the literature and this study would set the scene for a fertile area of research that the Department of Health and Aging [15,16] recognise as a key area in developing quality and establishing accountability in the aged care arena.

3. The pilot study offered a minor collaboration opportunity that facilitated a link between UWA and Swan Care Group. This may be useful in terms of support for future student clinical placements, training support for Swan Care Group staff and further research ventures.

4. In 2010 a similar study was undertaken with the St. John’s Ambulance service in Western Australia [13] Linking the results from this and previous research that offer interesting insights into the profile of clinical leaders in these diverse clinical fields [24].

5.2. Nursing leadership in the aged care environment

While many publications outline the role of effective management to address care and quality issues in the aged care sector, fewer publications were identified that outline the relevance of leadership in the aged care sector, although more and more appear to be evident as the significance of leadership issues are raised. In 2008, the Office of Aged Care Quality and Compliance released a report on residential care and suggested that aged care residential providers take a proactive role in promoting leadership in their facilities [15]. This was reinforced at the 'Better Practice in Aged Care' conference supported by the Aged Care Standards and Accreditation Agency, when it was suggested that visionary leadership was required to improve the lives of care home residents [16].

Other publications have linked developments in aged care leadership with improving the care and management of elderly resident's chronic pain [25] and with improvements in team work and communication [26]. Two Australian papers link leadership development with innovative practice in the aged care sector [27,28] and Jeon, Merlyn and Chenoweth offer the most extensive literature review of leadership and management in the aged care sector with a 'narrative synthesis' that finally identified 153 publications relevant to the topic of leadership and management and aged care [29]. This study concluded that the literature provided 'ample' evidence of the impact of management and leadership on matters of staff turnover, retention, leave and absenteeism. As well, the literature dealt in detail with management issues such as staff performance, staff organisational commitment, job satisfaction, productivity and care quality. However, they noted that little evidence of experimental studies existed and few studies dealt with 'leadership.' Indeed they concluded that while 'most' studies were conducted in the UK and North America, "no Australian study was found that describes a particular leadership program or model specifically designed for the residential aged care setting, thereby paving the way for a well-designed effective study in the future" [29].

Method

Aim

To explore the perceptions of leadership and approaches to leadership development of senior nurses and care home managers in one aged care residential facility in Perth, Western Australia.

Design

The methodological principles of the research rest upon descriptive phenomenology, a methodological approach that can be used to describe the everyday world of human experience [30]. This approach supports the use of purposive sampling for recruitment and allowed the researcher to “bracket” concepts, thus helping the researcher to reflect upon their own personal assumptions, biases, beliefs and attitudes about the phenomenon [30]. This study produced both qualitative (interviews) and quantitative (questionnaires) data.

Data collection

The principle methods employed to generate data in this study were a questionnaire and an interview. Questions for both methods were developed from the literature review, consultation with colleagues and past experience in the application of nursing leadership approaches in practice, all based on a similar UK study and study with the St. John Ambulance Service in Western Australia. The advantage of using interviews was that it allowed all the participants to offer their views and respond in a considered way to the questions asked. Although this approach is more expensive and more time consuming than other sampling methods, an interview, used in conjunction with the questionnaire allowed considerable depth of data to be secured and ensure a more personal approach to securing respondent participation. As well these methods facilitated an appropriate phenomenological approach to the study.

Ethical considerations

Ethical issues were in keeping with the National Health and Medical Research Council, Australian Code for the Responsible Conduct of Research (2007) [31]. Ethical approval was sought and secured through a university research ethics approval process and followed permission from the health agency. Confidentially for all
participants were respected and at no point did the researcher record the participant’s names or personal details. Each questionnaire was provided with an accompanying explanation letter outlining the research aims and addressing issues of confidentiality, ethical approval and the participant’s right to withdraw with impunity (by simply not returning the questionnaire). Each interview participant was offered the same set of questions to consider was provided with a consent form and an accompanying explanation letter outlining the research aims and addressing issues of confidentiality, ethical approval and the participant’s right to withdraw, again with impunity. No participant information in either the questionnaires or interviews was linked to individual respondents and participant anonymity has been assured. As well, it was made clear that the research was not related to the participant’s employment or work performance and any information of a confidential or sensitive nature was to be and has been kept secret and secure. All data remains securely locked in a file at the University of Western Australia where the primary researcher now works. Returned questionnaires will be destroyed after 5 years.

Data analysis

Interview data was analysed with the aid of an NVivo 0.6 computer program and with manual data configuration as required [32]. Questionnaire data was analysed with the aid of an SPSS computer program for quantitative data. This was achieved by following steps outlined by Smith, Flowers & Larkin [33]. These steps include; reading and re-reading, initial noting, developing emergent themes, searching for connections across emergent themes and examining levels of interpretation. The data collected from the interviews require the information to be broken down, examined, compared, conceptualised and categorised [34]. Each of these approaches focuses on different interpretations of the data as they are distinctive analytical processes [33–35].

Participants

Purposive sampling was used for selecting the participants from the senior nursing staff or care home managers of a large residential facility. There were 19 participant details provided at the beginning of the research study period (March 2012 to June 2012). Of these one left during the research period and two new participants were identified, bringing the final total to 20 senior nursing staff or care home managers. These 30% stated that they managed “the day-to-day management.” Of the 20 potential study participants, ten returned questionnaires (50%) and eight participants were interviewed (40%). Four participants completed the questionnaires and were also interviewed.

Limitations

This research was only offered as a pilot study and as such focused on only one residential facility. The funding for the study was limited, suggesting that while an adequate number of participants were recruited at the Swan Care Group facility in Bentley, a larger and wider study was not possible. Therefore, the limited sample size in the questionnaires could be seen as a limitation. As well, four of the senior nursing or care home manager staff at Swan Care Group, Bentley at the time of the study were male, no male staff returned questionnaires and only one male volunteered to be included in the interview group. As such, the views expressed are dominantly those of the female senior nursing and care home staff at the facility.

Findings

As two data methods were used (a questionnaire and interviews) the results from both of these methods are offered separately.

Findings - The Questionnaire

The questionnaire respondents average length of service with Swan Care, Bentley was just under 9 years (8.63 years) with the longest service of any respondent being 40 years (question 14). However, 4 of the respondents had worked at Swan Care for less than 12 months. The gender make-up of the respondents to the questionnaire showed that no male staff responded. This is not in keeping with the profile of men in nursing and indeed four of the senior nursing staff working at Swan Care, Bentley at the time of the study where men. They simply failed to respond to the questionnaire. The distribution of the ages of respondents shows that no respondent was below the age of 41, with 30% being between 41-50, 50% being between the age of 51-60 and 20% of respondents being over the age of 60.

This indicates that staff who responded to the questionnaire where all over the age of 41 and most were over 51, with one staff member indicating that they were 74 years of age.

No respondent indicated that they had any formal leadership training and only one respondent indicated that they had received some sort of management training.

How do you know a clinical leader? Respondents were offered a list of 54 attributes or descriptive words taken from a wide range of literature describing leaders (Table 1).

Participants were asked to indicate with a “tick” those characteristics/attributes they saw as “most” identifiable with clinical leaders. Table two lists the top 10 characteristics indicated by respondents (Table 2).

Other terms that may have been expected to be associated with leadership roles such as vision and creativity (both associated with transformational leadership) were selected much less commonly (40%) and (50%) respectively. Respondents were offered the same list of attributes (Table 1) and asked to indicate with a “cross” those characteristics/attributes they saw as “least” identifiable with clinical leaders (Table 3).

Other Qualities: Respondents were asked to suggest other qualities or characteristics of a clinical leader not on the list of 54 attributes. Few additional words were suggested although Trustworthy, Responsible, None-judgemental, Reliable, Enthusiastic, Experienced and Friendly were offered.

Their role: Half (50%) explained that they saw themselves as clinical leaders, because they thought they were, “experienced in their role” or identified their role with the facilitation of change. Few respondents (30%) thought their role called for them to engage in management. These 30% stated that they managed “the day-to-day operation,” “worked in a complex environment,” or “dealt with processes rather than people.” The majority of respondents (70%) indicated that they did not see themselves as managers, stating that they, “preferred working directly with residents and their families” or simply that they “preferred to work with people.” Implying that they saw managers as less, client / people focused.

Leadership capacity: All the respondents (100%) suggested that they were facilitated to lead and collaborate in clinical practice, with comments such as; “I am placed in a situation where I have to be a leader,” “part of my role is to work collaboratively” and “I am required to
provide clinical leadership across a number of facilities therefore I must lead and work collaboratively." However, few thought their colleagues saw them as clinical leaders, while most (60%) thought they were seen as both a leader and manager. When asked to offer a reason for their response, most indicated that they "were often the only member of staff that others could come to with issues," or that they "managed the operation on a day-to-day basis." Of the few that thought their colleagues did see them as a clinical leader, most suggest it was because they had, "relevant clinical experience," "had their colleagues' respect" or because "they were approachable and knowledgeable."

The difference between leadership and management: Half (50%) offered their views on the difference between leadership and management, indicating that leadership was; "being able to work alongside your colleagues," or about "leading by example," and was, "more directly involved with the floor level."

Management was described as being in an "overseer role," relating to "processes," offering direction or orders," "being removed from the day-to-day resident care" and "involved more corporate issues."

Barriers: Most (60%) indicated "yes," some (30%) indicating "no," but added no reason why and 1 person (10%) suggested they were "not sure" about barriers. When asked for the reasons for the barriers a number of responses were offered. These are included in Table 4.

Findings - The interviews

Interviews were conducted with eight participants (40% of the potential interviewees). Interviews were conducted on site, in a ward office or dining area and at a time that was convenient to the staff member. Each potential interviewee was approached either opportunistically, when the interviewer was on site or at a pre-arranged time following a phone call to make an appointment. No one was coerced into an interview and consent was sought in each case. Each interview undertaken was conducted within 60 minutes in order to limit the disruption to the participant's duties and responsibilities and four of those interviewed had also completed the questionnaire.

Questions focused on a number of areas identified as significant following an analysis of the questionnaire data and as a result of a predetermined field of enquiry about clinical leadership. Detailed demographic data was not recorded to aid in participant anonymity. 

The interviews were recorded and transcribed verbatim then subjected to a thematic analysis using an Nvivo 6.0 computer program [32]. This involved detailed analysis, reading and re-reading each interview and identifying categories, sub-themes and themes within the data that outlined and explained the interviewee's understanding of clinical leadership and other related issues. Six themes were identified from the data analysed (Tables 5 and 6).

**Theme 1:** The clinical leader's role: This theme grew from the sub-themes "clinical skills," "dealing with others" and "supervising and coordinating care at the bedside." These themes developed as respondents discussed their role at Swan Care Group, Bentley. In describing their role respondents suggested:

"I care for residents directly by providing medications and doing dressings and I have a hands on role in coordinating the activities of other carer staff and working as a link person with other disciplines or professionals."

Management activities were not mentioned and in general each respondent saw themselves as central to the delivery of clinical care and the coordination of care in general.

**Theme 2:** The difference between a manager and a leader: Categories identified to support this theme were sub-divided into "Leadership attributes" and "Manager attributes" with respondents identifying a range of attributes often in-keeping with the descriptive words identified in the questionnaire data that outlined their views of the key attributes for a leader or a manager within the aged care environment. Respondents suggested that:

"I think there is quite a lot of difference between a manager and a leader...a manager is more like...you know...saving money while leaders really look for quality."

Leaders were described as dealing with the quality of care and how care can be improved, with the bigger picture, people, and teams and with "hands on", floor work. Managers were described as "having authority and dealing with the day-to-day stuff" and "taking responsibility for the residents". Leaders were seen to be recognised as functioning at "any level". Managers though were described as being responsible for "ordering people to do things", while not always being seen to listen to staff. Mangers were described as "thinking differently

| Copes well with change | Is a motivator | Deals with routine |
| Sets direction (planning) | Is controlling | Is consistent |
| Considers relationships valuable | Has management experience | Copes well with Complexity |
| Flexible | Is a teacher | Is visible in practice |
| A guide | Is a mentor | Is a visionary |
| Sets goals and targets | Is a negotiator | Directs and helps people |
| Has integrity and is honest | Is responsible for others duty/responsibilities | Deals with reward/punishment |
| Is inspirational | Takes calculated risks | Aligns people |
| Is a critical thinker | Is a regulator | Counts on trust |
| Is creative/innovative | Is analytical | Deals with resources allocation |
| Is clinically competent | Is an administrator | Maintenance of relationships |
| Is artistic/imaginative | Is conservative | Inspires confidence |
| Is supportive | Is an advocate | Is articulate |
| Is a change agent | Is approachable | Is just/fair |
| Can be a decision maker | Is a coach | Manages staff |
| Has a healthy sense of humour | Is caring/compassionate | Is an effective communicator |
| Evaluates the performance of staff | Is a role model for others in practice | Resolves conflict |
| Works alone | Must have relevant postgraduate training | Is courageous |

Theme 3: Leadership Characteristics: Many characteristics were used to describe clinical leaders. These fell into a number of sub-themes that supported many of the attributes identified in the questionnaire aspects of the study. These themes suggested that clinical leaders needed;

"...communication skills, clinical skills and clinical knowledge and that you have to be visible in the ward area."

"Clinical leaders should act as a role model to others in the clinical area and work as part of the team and to be fair in their approach to others."

It was also suggested that clinical leaders could be identified at any level of the clinical team. In keeping with the questionnaire data “approachability” was identified as the most important characteristics of a clinical leader, while sound clinical and communication skills were seen as central to the ability of a clinical leader to function and be recognised as a clinical leader.

Theme 4: Preparation for the role: In response to questions about their preparedness for their role it is not surprising that respondents suggested they either felt “well prepared”, “not well prepared” or that “they could do with on-going education” to keep up-to-date. Most comments suggested that the respondents felt well prepared, by having previous experience, seminars and adequate university preparation, although a number of respondents sought further education or had had no formal preparation for their leadership role or any management functions they may have been required to undertake.

Theme 5: Getting involved: This theme resulted from questions about how they, as clinical leaders managed to encourage initiative and participation or involvement from their colleagues. In effect the respondents described how they could; “…support my colleagues to get involved in care or care focused initiatives by using clear communication.”

Clear communication included the issuing of orders as well as making clear what was expected of others, while some respondents recognised the value in “being positive toward others” and “getting to know people (as individuals) and not treating people like machines.” This lead to motivating and inspiring clinical staff by recognising the importance “of connecting with colleagues as individuals.”

Theme 6: Barriers to leadership potential: This theme resulted from direct questions about the barriers that clinical leaders faced in the aged care environment. A number indicated that they faced “no” barriers, but these views were rare. Most felt there were a number of barriers or “potential barriers.” Offered were sub-themes such as communication issues with poor English language skills dominant among them. As well as being difficult for some staff it was identified that some residents struggled with their capacity to understand some staff’s English expression or accent. This was an interesting observation during the data collection as on a number of occasions the researchers were unable to make them understood or gather quality data because of the respondent’s poor English language comprehension. “Low staff numbers” or “poorly qualified staff members” were identified by a number of respondents as barriers to the development of their leadership potential, as was limited access to learning support and a lack of clarity around staff roles. Some respondents felt that staff numbers were not as much of an issue as much as access to (or support from) staff with higher qualifications who they could “bounce ideas off” or share ideas for further development. Also identified was a lack of time to carry out certain roles. Some staff also acknowledged that the barriers to their leadership development were "personal and reflected their own limited motivation to engage with on-going professional development.”

Discussion

The discussion is a considered reflection of the results from the questionnaires, interviews, researcher’s observations and literature informing an understanding of leadership within the Swan Care Group, Bentley facility.

With a return rate from the questionnaire of 50% and the interview rate of 40% it can be assumed that a considerable number of the senior nursing and care home management staff at Swan Care Group, Bentley expressed opinions and views about the topic of clinical leadership. As only four participants undertook both the questionnaire and interview it can be stated that the research has covered a substantial number of the senior nursing and care home management staff and as such offers valid and detailed research data.

Between March and June 2012 there was a potential of 20 senior nurses or care home managers that could have taken part in both aspects of the study. Demographic data was not collected during the interviews to aid in participant anonymity. The questionnaire data suggested that the average senior nurse or care home manager had...

worked at Swan Care Group, Bentley for just less than 9 years with one
respondent having worked at the facility for 40 years, while 4 of the 10
questionnaire respondents had worked at Swan Care Group, Bentley
for less than 12 months. Significantly, the participants who responded
to the questionnaire where all over the age of 41 with most being over
the age of 51 with all eight of the staff interviewed sitting within the 41-
51 age bracket. Unlike the questionnaire data the interviews included
the views of one male, with the remaining interviewees being female.

The results of this study indicated that the attributes and
characteristics of clinical leaders identified by the participants in the
study are consistent with results from other, similar studies from other
health care fields [11,13,24]. Approachability, good clinical skills,
clinical knowledge, honesty, integrity, support for others and visibility
in the clinical area being dominant attributes of the clinical leaders. It
was also noted that participants saw a distinction between leadership
and management and that their more clinically focused roles led them
toward a greater focus on leadership. However, few had any leadership
instruction and almost all saw barriers that hindered the development or
application of leadership in the care home environment (Table 4).

Few of the participants saw themselves as managers, although a
few indicated that they sometimes undertook management functions.
This was consistent with the research results of Cook [36] who
suggested that clinical leaders were likely to come from across the
spectrum of staff but more likely to be from staff with a clinical, rather
than management focus. The majority of those interviewed said that
they preferred to work directly with residents in a clinical capacity
and that this was incompatible with a manager’s role, adding that they
saw themselves as being clinically skilled and clinically focused or
coordinating care through others. Only a few of the respondents to the
questionnaire thought their colleagues saw them as clinical leaders. In
the original nursing research [10,11] and later research with ambulance
staff [13,24] the majority of those nominated as clinical leaders by their
colleagues failed to recognise themselves as such. Therefore, while
clinical leaders are evident in clinical practice in significant numbers
[11] many fail to recognise either themselves or their colleagues as
leaders if they do not hold a management position or title.

Most of the interview participants failed to mention “management” as
a significant aspect of their role and all felt themselves drawn to the
delivery of clinical care and the coordination of care by others as the key
attributes of their role. The net result was that while few participants
saw themselves as managers (even if others may have), most failed to
recognise themselves as clinical leaders either, leaving them to
occupy a sort of limbo position between leadership and management
and having, as a result, limited authority or power to effectively lead
if needed or manage if desired. Many participants failed to recognise
themselves as clinical leaders and some seemed to suffer from a degree
of role ambiguity as a result [32].

It was significant that none of the respondents to the questionnaire
or interviews discussed any formal leadership or management
instruction or education and most if they had gathered information on
the topic of leadership, had done so simply by picking it up along their
career journey.

All of the interviewees indicated that they saw their role as relating to
that of a clinical leader and not a manager. Most of the questionnaire
and interview data suggested that participants did not see themselves
as managers because they saw managers dealing with authority and
finances, and themselves dealing more with people, other staff, and
the coordination of care or the delivery of direct resident care. Less
clinically focused staff (managers) where not regarded as fitting the
description of a clinical leader and they were classified clearly as having
more management responsibilities. These findings are consistent with
other research results [11,13,24,36,37] and confirmed the view that
clinical leaders could be found at any level of the organisation as long
as their role involved a substantial clinical focus and attention to direct
resident care or the coordination of those who delivered direct resident
care. Participants involved in this study could be described as clinical
leaders, even though a few saw themselves as managers and most had
a limited insight into their limbo clinical role or pseudo-management
responsibilities.

Most of the respondent’s highlighted barriers that stopped them
implementing leadership (Table 4). Few of these problems seem
insurmountable, however for them to be overcome, barriers need to be
recognised and addressed openly and with considerable consultation. A
key feature of the study was to identify the qualities and characteristics
of clinical leaders in the aged care setting. As such, respondents and
interviewees were offered an opportunity to rate and describe the
characteristics they associated “most” or “least” with clinical leaders.
The results were consistent with the results from other studies related
to clinical leadership attributes [10,11,13,24,37] and are outlined in
Table 1. The interviews re-enforced these attributes describing clinical
leaders as having good communication skills, sound clinical skills and
clinical knowledge, being visible in practice, acting as role models,
being fair and approachable and working within and as part of a team.
Approachability was sighted as the most important characteristic and
in the questionnaires and again in-keeping with the two previous
studies [10,11,13] being seen as “controlling” was considered the least
favourable clinical leader attribute. Most interviewees while prepared
for their clinical role were commonly unprepared for their leadership
responsibilities (or indeed management tasks if these were required).

Clinical leaders are (in part) recognised because they support and
motivate others, although few participants saw themselves as clinical
leaders or genuinely understood their role as clinical leaders. Most felt
clear communication, the possession of sound clinical experience and
the ability to treat people with respect or be positive toward people were
all that were needed to motivate and support others to get involved in
making care better. While these approaches are essential, little more
than these approaches was discussed and as such the potential for
greater innovation or capacity to improve care seemed minimal. If
clinical leaders are to genuinely impact on the quality of care and make
care better they need to have a clear understanding of how to motivate
others and build their team’s capacity. The researcher’s noted that
while often underestimated by the participants in the study, the barriers
discussed seemed more in evidence than was acknowledged offering a
possible reason for the limited motivational or innovative approaches
discussed.

The implications for nursing practice include; undertaking a wider
investigation of the perceptions of clinical leadership and approaches
to leadership development for senior nurses and care home managers
in other aged care residential facilities. Initiating a training program
to support the development, understanding and application of clinical

leadership with an emphasis on the development of skills related to a range of issues such as: understanding the difference between leadership and management, understanding clinical leadership, managing change, clinical decision making, team working, networking and delegation, conflict management, motivation, the leader’s role in quality management and issues of empowerment. Further suggestions are to develop strategies for dealing with staff whose English language skills were poor or need to be developed further. It was also noted that participants in the study were generally of advancing age and while not a focus of the study it is suggested that this is in urgent need of attention.

Conclusion

This study has offered a set of data from questionnaires and interviews with senior nursing staff and care home managers at a residential care facility. The study sought to investigate the perceptions of clinical leadership and approaches to leadership development. Participants were able to express their understanding of clinical leadership and describe the characteristics or attributes they saw as vital for a clinical leader. Also offered, was data about how leadership skills were obtained and insights into the difference between leadership and management. Participants were also able to identify the issues that may hinder or stifle clinical leadership development in the aged care environment and recommendations and suggestions were made that have implications for nursing practice.
